Methods

We studied 15,428 adults aged 45–64 years, in four US communities, who completed a dietary questionnaire at enrolment in the Atherosclerosis Risk in Communities (ARIC) study (between 1987 and 1989), and who did not report extreme caloric intake (≤600 kcal or ≥4200 kcal per day for men and ≤500 kcal or ≥3600 kcal per day for women). The primary outcome was all-cause mortality. We investigated the association between the percentage of energy from carbohydrate intake and all-cause mortality, accounting for possible non-linear relationships in this cohort. We further examined this association, combining ARIC data with data for carbohydrate intake reported from seven multinational prospective studies in a meta-
Interpretation

Both high and low percentages of carbohydrate diets were associated with increased mortality, with minimal risk observed at 50–55% carbohydrate intake. Low carbohydrate dietary patterns favouring animal-derived protein and fat sources, from sources such as lamb, beef, pork, and chicken, were associated with higher mortality, whereas those that favoured plant-derived protein and fat intake, from sources such as vegetables, nuts, peanut butter, and whole-grain breads, were associated with lower mortality, suggesting that the source of food notably modifies the association between carbohydrate intake and mortality.
The low-carbohydrate diet and cardiovascular risk factors: evidence from epidemiologic studies

Conclusions: Recent randomized controlled trials document that low-carbohydrate diets not only decrease body weight but also improve cardiovascular risk factors. In light of this evidence from randomized controlled trials, dietary guidelines should be re-visited advocating a healthy low carbohydrate dietary pattern as an alternative dietary strategy for the prevention of obesity and cardiovascular disease risk factors.

Weight Loss Results From Published Randomised Controlled Trials (RCTs) Between Low-Carb & Low-Fat Diets

- 58 studies show greater weight loss in the Low-Carb group.
- 36 studies show significantly greater weight loss in the Low-Carb group.
- 7 studies show weight loss in the Low-Fat group.
- 0 studies show significantly greater weight loss in the Low-Fat group.

67 RCTs in total (2 are equal).
Limit on Saturated Fats is Unnecessary, says “State-of-the-Art Review” in Journal of American College of Cardiology. ... The JACC abstract reads: “The recommendation to limit dietary saturated fatty acid (SFA) intake has persisted despite mounting evidence to the contrary.  Jun 24, 2020
What to Eat with Diabetes or Prediabetes: ADA's New Nutrition Guidelines
### Overview of Eating Patterns

#### Mediterranean-Style

**Description:** Emphasizes plant-based food (vegetables, beans, nuts, and seeds, fruits, and whole intact grains); fish and other seafood; olive oil as the principal source of dietary fat; dairy products (mainly yogurt and cheese) in low to moderate amounts; typically fewer than 4 eggs/week; red meat in low frequency and amounts; wine in low to moderate amounts; and concentrated sugars or honey rarely.

**Potential benefits:** Reduced risk of diabetes, A1C reduction, lower triglycerides, reduced risk of major cardiovascular events

#### Very Low-Fat

**Description:** Emphasizes fiber-rich vegetables, beans, fruits, whole intact grains, nonfat dairy, fish, and egg whites and comprises 70–77% carbohydrate (including 30–60 g fiber), 10% fat, 13–20% protein.

**Potential benefits:** Weight loss, lowered blood pressure

#### Low-Carbohydrate

**Description:** Emphasizes vegetables low in carbohydrate (such as salad greens, broccoli, cauliflower, cucumber, cabbage, and others); fat from animal foods, oils, butter, and avocado; and protein in the form of meat, poultry, fish, shellfish, eggs, cheese, nuts, and seeds. Some plans include fruit (e.g., berries) and a greater array of non-starchy vegetables. Avoids starchy and sugary foods such as pasta, rice, potatoes, bread, and sweets. There is no consistent definition of "low" carbohydrate. In this review, a low-carbohydrate eating pattern is defined as reducing carbohydrates to 26–45% of total calories.

**Potential benefits:** A1C reduction, weight loss, lowered blood pressure, increased HDL-C and decreased triglycerides

#### Very Low-Carbohydrate

**Description:** Similar to low-carbohydrate pattern but further limits carbohydrate-containing foods, and meals typically derive more than half of calories from fat. Often has a goal of 20–50 g of non-fiber carbohydrate per day to induce nutritional ketosis. In this review a VLC eating pattern is defined as reducing carbohydrate to less than 25% of total calories.

**Potential benefits:** A1C reduction, weight loss, lowered blood pressure, increased HDL-C and decreased triglycerides

#### DASH

**Description:** Emphasizes vegetables, fruits, and low-fat dairy products; includes whole intact grains, poultry, fish, and nuts reduced in saturated fat, red meat, sweets, and sugar-containing beverages. May also be reduced in sodium.

**Potential benefits:** Reduced risk of diabetes, weight loss, lowered blood pressure

#### Paleo

**Description:** Emphasizes foods theoretically eaten regularly during early human evolution, such as lean meat, fish, shellfish, vegetables, eggs, nuts, and berries. Avoids grains, dairy, salt, refined fats, and sugar.

**Potential benefits:** Mixed results and inconclusive evidence

In summary:

1) RCTs = Improved metabolic markers. LC>LF
2) Journal of the College of Cardiology embraces saturated fat
3) ADA recommends low and very low carb diets
4) AACE/ACE recommend low-carb
Why carb restriction has the potential to transform your clinical practice
Only 12 percent of American adults are metabolically healthy, Carolina study finds

Only 1 in 8 Americans are achieving optimal metabolic health, which carries serious implications for public health.

By the UNC Gillings School of Global Public Health, Wednesday, November 28th, 2018

Exterior view of the Michael Hooker Research Center at the UNC Gillings School of Global Public Health on March 1, 2018, in Chapel Hill. (Johnny Andrews/UNC-Chapel Hill)

Results: Changing from ATP III (Adult Treatment Panel III) guidelines to more recent cut points decreased the proportion of metabolically healthy Americans from 19.9% (95% confidence interval [CI]: 18.3-21.5) to 12.2% (95% CI: 10.9-13.6). Dropping WC from the definition increased the percentage of adults with optimal metabolic health to 17.6%. Characteristics associated with greater prevalence of metabolic health were female gender, youth, more education, never smoking, practicing vigorous physical activity, and low body mass index. Less than one-third of normal weight adults were metabolically healthy and the prevalence decreased to 8.0% and 0.5% in overweight and obese individuals, respectively.

Conclusions: Prevalence of metabolic health in American adults is alarmingly low, even in normal weight individuals. The large number of people not achieving optimal levels of risk factors, even in low-risk groups, has serious implications for public health.

The background of therapeutic carb restriction
Who should consider carb restriction? These guidelines are meant to be applied as a dietary intervention for specific conditions for which carbohydrate reduction has been shown to offer therapeutic benefits.

- **Rapid physiologic changes** can be expected, and medication management must be timely to avoid predictable interactions between these changes and common medications.

- A well-formulated carbohydrate-restricted diet includes adequate energy, protein, fat, vitamins, and minerals. With adequate protein and fat, the dietary requirement for carbohydrate is zero (Institute of Medicine [U.S.], 2005; Westman, 2002).

- Even when no dietary carbohydrate is consumed, glucose-dependent tissues are able to utilize glucose produced through gluconeogenesis and glycogenolysis (Westman et al., 2007).

- Because dietary carbohydrate is not essential, it need not be a primary focus for certain therapeutic nutritional interventions.
Background

- **VLCK** (very low-carbohydrate ketogenic) diets recommend 30g or less of dietary carbohydrate per day (Hallberg et al., 2018).
- **LCK** (low-carbohydrate ketogenic) diets recommend 30-50g of dietary carbohydrate per day (Saslow et al., 2017).
- **RC** (reduced-carbohydrate) diets recommend 50-130g of dietary carbohydrate per day, a level that is higher than levels listed above and lower than the U.S. DRI for carbohydrate. Deliberate restriction of kcals may or may not be recommended at this level.
- Recommendations for deliberate kcal restriction are not typically part of VLCK and LCK clinical interventions but may be used in research protocols.
The Dietary Guidelines for Americans recommends that carbohydrates make up 45 to 65 percent of your total daily calories. So, if you get 2,000 calories a day, between 900 and 1,300 calories should be from carbohydrates. That translates to between 225 and 325 grams of carbohydrates a day.
The therapeutic potential of therapeutic carb restriction
The therapeutic potential of therapeutic carb restriction

- Therapeutic carbohydrate restriction can assist in improving all aspects of the metabolic syndrome, in part by helping to reduce blood glucose levels, which in turn can reduce fasting and postprandial insulin levels and improve insulin resistance (Volek & Feinman, 2005).

- The appropriate level of carbohydrate restriction to meet therapeutic goals will differ among patients. An amount of less than 50g of carbohydrate per day frequently leads to a general change in metabolism from “glucocentric” (where glucose is relied on as a primary energy source) to “adipocentric” (where ketone bodies and fatty acids are primary energy sources), although this level varies across individuals (Westman et al., 2007).
The therapeutic potential of therapeutic carb restriction

- With regard to **hypertension**, high circulating levels of insulin that accompany insulin resistance have been associated with sodium retention, proliferation of vascular smooth muscle, increased sympathetic nervous system activity, and diminished release of nitric oxide from the endothelium (Hsueh, 1991; Yancy et al., 2010). By reducing insulin levels, reducing carbohydrate intake may be expected to improve blood pressure and to have an effect on fluid and electrolyte balance.

- With regard to **dyslipidemia**, high circulating levels of insulin have been associated with increased plasma triglyceride (TAG) concentration, decreased high-density lipoprotein (HDL) cholesterol concentration, and increased levels of atherogenic small dense particles of low-density lipoprotein (LDL) cholesterol (Ferrannini, Haffner, Mitchell, & Stern, 1991; Reaven, Chen, Jeppesen, Maheux, & Krauss, 1993). Reducing carbohydrate may improve the TAG/HDL ratio and certain markers of inflammation (Forsythe et al., 2008).

- **Nutritional ketosis** may be a contributing factor in reducing appetite (Gibson et al., 2015).
How to initiate therapeutic carb restriction
Good candidates are patients with metabolic conditions (see Paoli, Rubini, Volek, & Grimaldi, 2013; Mardinoglu et al., 2018).

Patients should also be able and prepared to use a blood glucometer to check serum glucose if on insulin or insulin secretagogues (sulfonylureas and meglitinides) and to communicate with the health care team during the diet intervention (Cucuzzella, Hite, Patterson, & Heath, 2019).

The intervention should be individualized with regard to the patient’s existing nutrition habits, resources, living arrangements, and roles (i.e. who does the cooking and food purchasing).
Laboratory tests as indicated for the presenting condition should be completed to rule out acute pathology and establish baseline metrics.

- Blood tests:
  - Complete blood count (CBC)
  - Fasting comprehensive metabolic panel (CMP), including:
    - Glucose
    - Electrolytes
    - Kidney function
    - Acid-base balance
  - Fasting lipid panel, including HDL cholesterol and triglycerides
  - Thyroid-stimulating hormone (TSH)
  - Hemoglobin A1c (HbA1c)
  - Liver function (including gamma-glutamyl transferase [GGT])

- Urine tests:
  - Urine albumin: creatinine ratio

Other tests that may be considered:
- Fasting total insulin
- Homeostatic model of insulin resistance (HOMA-IR)
- Postprandial insulin assay/Kraft protocol (if available and affordable)
- Full thyroid function panel, including TSH, fT3, fT4, RT3 and antibodies
- Vitamin D
- High-sensitivity C-reactive protein (hsCRP)
- Advanced lipid panel
- Glucose tolerance testing (GTT)
- Peak flow test
- Erythrocyte sedimentation rate (ESR)
- Serum uric acid
- Coronary calcium score - for risk stratification and ongoing monitoring
- C-peptide levels - for patients who are on insulin, to ensure that the patient is still making insulin (see Section 6.1 below).
Because of concerns regarding de-prescribing pharmacological therapies, the following conditions require close, frequent medication review when therapeutic carbohydrate reduction is used: • Type 1 diabetes mellitus • Type 2 diabetes mellitus • Hypertension • Chronic kidney disease

The concern is that “high” protein levels may impair renal function, but there is little evidence to suggest that protein intakes at the levels consumed on a low-carbohydrate diet are harmful for people with moderately decreased kidney function. For patients with advanced kidney disease, the recommendation for therapeutic carbohydrate restriction must be made on a case by case basis, as the standard “renal diet” may conflict with a low-carbohydrate diet in some regards.

Patients with history of gout are at a higher risk of flare when transitioning to the diet, although long-term gout flares may improve on low-carb diets (Steelman & Westman, 2016). Consider prophylactic allopurinol during transition.
Some side effects of a low-carbohydrate diet such as lightheadedness, fatigue, and headache are due to low body salt and hypotension, especially in patients on blood pressure-lowering therapy. High levels of insulin may cause the kidneys to retain salt and water (Brands & Manhiani, 2012). When insulin levels are lowered due to either reduced insulin dose or reduced insulin secretion because of reduced carbohydrate consumption, this can cause diuresis and symptomatic hypotension. Unless there is a history of heart failure or salt-sensitive hypertension, patients should not restrict sodium on low-carbohydrate diets and will likely need additional sodium and hydration, especially in the first several weeks. For most patients, 2-3g of sodium (or 5-7g of salt) per day is appropriate. This can be accomplished by salting food liberally, or sodium can be supplemented by advising patients to sip on a broth made with regular sodium bouillon cubes (Steelman & Westman, 2016).
How to adjust medications, monitor, and evaluate for follow-up
How to adjust medications

- If patients are on insulin or sulfonylureas when beginning a low-carbohydrate diet, it is recommended that doses be reduced immediately to prevent hypoglycemia.
- Thiazolidinediones may be stopped because they contribute to weight gain but are unlikely to cause hypoglycemia.
- DPP-4 inhibitors and GLP-1 analogues are safe to use, however SGLT-2 inhibitors should be used with caution because they can exacerbate dehydration and have been associated with diabetic ketoacidosis (DKA) episodes.
- It is recommended that SGLT2-i be stopped if a very low-carbohydrate diet is to be followed.
- Metformin can be used effectively in conjunction with a low-carb diet (Steelman & Westman, 2016). Metformin does not present the same risks of hypoglycemia as insulin or sulfonylureas.
How to adjust medications

- Blood pressure will need to be monitored in the clinic, ideally every 2-4 weeks during initiation of the dietary intervention.
- In addition, patients should be shown how to self-monitor blood pressure and be made aware of symptoms of low blood pressure, such as light-headedness upon standing or severe Clinical Guidelines for Therapeutic Carbohydrate Restriction https://www.lowcarbusa.org/clinical-guidelines/ Version 1.3.8 – Published September 25, 2020 Page 15 of 20 fatigue.
- These symptoms and/or systolic blood pressure below 120 should prompt reduction of anti-hypertensive medication.
How to adjust medications

- Warfarin doses may need to be adjusted and INR should be monitored more frequently during the diet transition (Steelman & Westman, 2016). Medications that have a narrow therapeutic range such as valproic acid (Depakote) and lithium should be monitored for potential dosing changes. Medications that interfere with lipolysis should be replaced or discontinued if possible, including: niacin, beta blockers, antidepressants, and antipsychotics.

- After the initiation of therapeutic carbohydrate reduction, the patient should be advised to check blood pressure and, if applicable, blood glucose daily, including some post-prandial readings 1-2 hours after a meal. Having tools available so that patients can track medication, blood pressure, and glucose is indispensable to providing a safe transition to a low-carbohydrate diet.
How to adjust medications

- Because dietary carbohydrate is not an essential nutrient, a well-formulated, low-carbohydrate diet that includes a variety of vegetables presents no health risks from nutritional deficits.
- Whether and in what manner to allow additional dietary carbohydrate into the diet will be an individual decision. It is unlikely that a return to previous levels of carbohydrate consumption would be recommended; to do so would likely lead to a return of previous health conditions that reduction of dietary carbohydrate ameliorated.
Resources
## Foods to Have

### Protein
- Seafood: All (including shellfish)
- Red Meat: Beef, bison, buffalo, lamb, elk, venison
- Poultry: chicken, turkey, eggs, duck, pheasant
- Pork: bacon, sausage, ham (low sodium)
- Dairy: cheese, cream, raw, milk, yogurt
- Organ Meats: All

### Herbs
- Anise
- Ashwaganda
- Basil
- Chamomile
- Coriander
- Echinacea
- Ginseng
- Kava Kava
- Lemongrass
- Oregano
- Peppermint
- Sage
- Thyme
- Turmeric
- Valerian

### Fruit
- Lemon/Lime
- Berries (1/2 cup per day max)
- Granny Smith Apple (1/2 per day max)
- Grapefruit (1/2 per day max)

### Nuts & Seeds
- Almonds
- Almond Milk
- Almond Butter
- Brazil Nuts
- Cashews
- Chia Seeds
- Flax Seeds
- Hazelnuts
- Macadamia Nuts
- Pecans
- Pine Nuts
- Pistachios
- Pumpkin Seeds
- Walnuts
- Sesame Seeds
- Sunflower Seeds

### Vegetables
- Collard Greens
- Cucumber
- Garlic
- Green Beans
- Greens
- Kale Leeks
- Lettuce
- Mushrooms (all)
- Swiss Chard
- Okra
- Onion/Shallots
- Radish
- Rhubarb
- Snow Peas
- Spaghetti Squash
- Spinach
- Sprouts (all types)
- Sugar Snap Peas
- Summer Squash
- Watercress
- Zucchini

### Fats
- Animal Fats*
- Chocolate/Cacao/Cocoa
- Avocado
- Avocado Oil
- Coconut Milk (canned)
- Butter*
- Coconut: Oil, Butter, Meat, Flakes
- Ghee*
- Extra-Virgin Olive Oil
- Bone Broth and Stews*
- Olives (all)

*Whenever possible, choose wild caught fish, organic, and grass fed
## Foods to Have in Moderation

**Vegetables**
- Max of 1/2 cup every 3 days
- Acorn Squash
- Beets
- Butternut Squash
- Delicate Squash
- Jicama
- Parsnips
- Pumpkin
- Rutabaga
- Sweet Potatoes
- Yams

**Fruit**
- Max of 1/4 cup per day
- Apricots
- Bananas
- Cherries
- Dates/Figs
- Grapes (red/green)
- Mango
- Melon
- Nectarines
- Oranges
- Papaya
- Peaches
- Pears (all types)
- Pineapple
- Plum
- Pomegranate
- Star Fruit
- Tangerines
- Tomatoes
- Watermelon

## Foods to Avoid

**Protein**
- Meats with added sugar, MSG, sulfites or carrageenan
- Quinoa
- Beans (black/red)
- Rice
- Buckwheat
- Chickpeas
- Lentils
- Oats

**Grains/Legumes**
- Dried Fruit

**Refined Carbohydrates**
- Bread
- Bagels
- Breadsticks
- Brownies
- Cake/Cupcakes
- Candy
- Cereal/Granola
- Chips
- Cookies
- Couscous
- Crackers
- Croissants
- Muffins
- Pasta
- Pastries
- Pita Bread
- Pizza
- Rolls
- Tortillas
- Tortilla Chips

## Quick Reference

- Drink 4 to 8 cups of water daily
- Include healthy fats with every meal (butter, oils: olive, avocado, coconut)
- No sugar, processed foods, or grains
- No hydrogenated oils like margarine and vegetable oil shortenings
- Maximum of 1-2 servings of fruit or starchy veggies daily
- No fast foods

Clinical Guidelines

These guidelines provide clinicians with a general protocol for implementing therapeutic carbohydrate restriction as a dietary intervention in hospitals or clinics. These guidelines are meant to be applied as a dietary intervention for specific conditions for which carbohydrate reduction has been shown to offer therapeutic benefits.
